Abstract. This article presents a test based on quadratic form using Type-2 with replacement-censored sample for testing exponentiality against weibull IFR/DFR alternative. The percentile points and powers are simulated. The proposed test is compared with that of Bain and Engelhardt (1986) test. An example based on Type-2 censoring is also discussed.

1 Introduction

The weibull distribution is defined by the pdf

\[ f(x; \theta, \beta) = \frac{\beta}{\theta} x^{\beta-1} e^{-x^{\beta}/\theta}, \quad x > 0, \quad \theta, \beta > 0 \]  

(1.1)

This distribution is quite popular as a life testing model and for many other applications where a skewed distribution is required. This model includes the exponential distribution with constant failure rate (CFR) for \( \beta = 1 \) and provide an increasing failure rate (IFR) for \( \beta > 1 \)

Key words and phrases: Conditional distribution, nuisance parameter, percentile points, power of the test, shape parameter, weibull distribution.
and decreasing failure rate (DFR) for $\beta < 1$. Hence test for $\beta$ is of interest.

Thoman et.al. (1969) have considered the problem of testing of hypothesis regarding the shape parameter based on complete samples. Bain and Engelhardt (1986) have proposed a modified version of Thoman et.al. (1969) test statistic whose asymptotic distribution is approximated to a chi-squared distribution. Lawless (1982), Bain and Engelhardt (1991) have discussed the problem of estimation and testing of shape parameter under Type-2 without replacement censoring and Type-1 censoring schemes. Very recently Muralidharan and Shanubhogue (2004) have obtained conditional test for Weibull DFR alternatives based on without replacement censored scheme. But there is less work done in the case of Type-2 with replacement censoring scheme because of complexity of finding distributions of the statistics obtained. In this article we propose a computationally simple test for testing $H_0 : \beta = 1$ against $H_1 : \beta > 1$ (or $H_1 : \beta < 1$) using Type-2 with replacement censored samples. The proposed test is also compared with that of Bain and Engelhardt (1986) test.

2 Derivation of the test

Many times observations of failures are naturally occurring in order. In this case, it is convenient to terminate the experiment after observing the first $r$ failures from $n$ units by replacing each failed item with a new item. In this section we derive a test statistic based on a Type-2 with replacement sample and study its properties.

Let $X(1) \leq X(2) \leq \cdots \leq X(r)$, $r \leq n$, be a Type-2 with replacement-censored samples of a complete sample of size $n$ from (1.1). Then the joint density is given by

$$f_X(x; \theta, \beta) \propto f(x(1)) f(x(2) - x(1)) \cdots f(x(r) - x(r-1)) [F(x(r))]^{n-1}.$$ 

Let $Y_i = X_i^\beta$, $i = 1, 2, \ldots, n$ then $Y_i$ follows an exponential distribution with density function

$$f_{Y_i}(y; \theta) = (1/\theta) e^{-y/\theta}, \quad y > 0, \theta > 0.$$ 

Let $Y(1) \leq Y(2) \leq \cdots \leq Y(r)$ be the corresponding type-2 with replacement-censored samples. Then

$$f_Y(y; \theta) = (n/\theta)^r e^{-ny(r)/\theta}, \quad 0 < Y(1) \leq Y(2) \leq \cdots \leq Y(r) < \infty.$$
For known $\beta$, $T = Y(\tau)$ is the complete sufficient statistic for $\theta$. By making the transformation $Z_i = Y_i - Y_{i-1}$, $Y(0) = 0$, $i = 1, 2, \ldots, r$, we get $\sum_{i=1}^r Z_i = Y(\tau)$. Hence (2.2) reduces to

$$f_{Z}(z; \theta) = \frac{(n/\theta)^{r} e^{-n \sum_{i=1}^{r} z_i/\theta}}{\prod_{i=1}^{r} \theta^{z_i/\theta}}.$$  

Therefore $Z_i$'s are i.i.d exponential with parameter $(\theta/n)$ and hence $Y(\tau)$ is gamma with parameter $(\theta/n)$ and $r$. Then the conditional pdf of $Y(1), Y(2), \ldots, Y(r-1)$ given $T = t$ is obtained as

$$f(Y(1), Y(2), \ldots, Y(r-1)|T = t) = \frac{\Gamma(r)}{t^{r-1}},$$  \hspace{1cm} (2.3)

$$0 < Y(1) \leq Y(2) \leq \cdots \leq Y(r-1) < t$$

It is seen that this conditional density does not depend on the nuisance parameter $\theta$. Hence we derive the test statistic for testing $H_0$ versus $H_1$ by treating the observations have come from (2.3). For this, we consider the quadratic form $Q = (\mathbf{Y} - \mu_0')\Sigma_0^{-1}(\mathbf{Y} - \mu_0)$, where $\mathbf{Y}' = (Y(1), Y(2), \ldots, Y(r-1))$, $\mu_0' = (\mu_1, \mu_2, \ldots, \mu_{r-1})$; $\mu_i = E_{i0}(Y(i)|T = t)$ and $\Sigma_0 = ((\mu_{ij}))$ is the conditional variance-covariance matrix of $\mathbf{Y}$ given $T = t$ computed under $H_0$. They can be obtained as follows:

We know that $Z_i$'s are i.i.d exponential random variables with mean $(\theta/n)$ and $\sum_{i=1}^r Z_i = t$. Then the pdf of $Z_i$ given $T = t$ is

$$f_{Z_i|T}(z_i|t) = \frac{(r-1)}{t} \left(1 - \frac{z_i}{t}\right)^{r-2}, \hspace{1cm} 0 < z_i < t$$  \hspace{1cm} (2.4)

and

$$f_{Z_i, Z_j|T}(z_i, z_j|t) = \frac{(r-1)(r-2)}{t} \left(1 - \frac{z_i}{t} - \frac{z_j}{t}\right)^{r-3}, \hspace{1cm} 0 < z_i + z_j < t.$$  

According to the theorem 1.6.7 of Reiss (1989), the distribution of the vector $(Z_1|T, Z_2|T, \ldots, Z_r|T)'$ is the same as that of $(V_1, V_2, \ldots, V_r)'$ where $V$'s are the spacings of a random sample of size $r$ from the uniform distribution on $(0, 1)$. Further, the author has given the asymptotic distribution of this vector of spacings and other related results (see corollary 1.6.10 of Reiss (1989)).

From (2.4) we obtain the moments of $Z_i|t$. Since $Y(i) = \sum_{j=1}^{i} z_j$, under $H_0$

$$\mu_i = E_{H_0}(Y(i)|t) = \sum_{j=1}^{i} E(Z_j|T = t) = \frac{it}{r}$$  \hspace{1cm} (2.5)
\[
\sigma_{ii} = VH_0(Y(i) | t)
\]
\[
= VH_0\left(\sum_{j=1}^{i} Z_j | T = t\right)
\]
\[
= \sum_{j=1}^{i} VH_0(Z_j | T = t) - \sum_{j \neq k} VH_0(Z_j | T = t) / (r - 1)
\]
\[
= \frac{i(r - i)v}{(r - 1)}, \quad (2.6)
\]

and

\[
\sigma_{il} = COV_{H_0}(Y(i), Y(l) | t)
\]
\[
= \sum_{j=1}^{i} \sum_{k=1}^{l} COV(Z_j, Z_k | T = t)
\]
\[
= \sum_{j=1}^{i} VH_0(Z_j | T = t) - \frac{1}{(r - 1)} \sum_{j=1}^{i} \sum_{j \neq k=1}^{l} VH_0(Z_j | T = t)
\]
\[
= \frac{i(r - l)v}{(r - 1)}, \quad (2.7)
\]

\(i = 1, 2, \ldots, r - 1; \quad l = 1, 2, \ldots, r - 1, \quad i < l\) and

\[v = VH_0(Z_j | T = t) = \frac{(r - i)t^2}{r^2(r + 1)}.\]

Using (2.6) and (2.7), the variance-covariance matrix \(\Sigma_0\) of \((Y | T = t)\) under \(H_0\) is

\[
\Sigma_0 = \frac{v}{r - 1} \begin{bmatrix}
    r - 1 & r - 2 & r - 3 & \cdots & 1 \\
    r - 2 & 2(r - 2) & 2(r - 3) & \cdots & 2 \\
    r - 3 & 2(r - 3) & 3(r - 3) & \cdots & 3 \\
    \vdots & \vdots & \vdots & \ddots & \vdots \\
    1 & 2 & 3 & \cdots & r - 1
\end{bmatrix}.
\]

Using Graybill (1969, pp.181), we get the inverse of \(\Sigma_0\) as

\[
\Sigma_0^{-1} = \frac{r^2(r + 1)}{t^2} \begin{bmatrix}
    2/r & -1/r & 0 & \cdots & 0 \\
    -1/r & 2/r & -1/r & \cdots & 0 \\
    0 & -1/r & 2/r & \cdots & 0 \\
    \vdots & \vdots & \vdots & \ddots & \vdots \\
    0 & 0 & 0 & \cdots & 2/r
\end{bmatrix}
\]
Substituting the values of $\mu_i$ and $\Sigma_{ij}^{-1}$ in the expression for $Q$ and on simplification, we obtain the test statistic as

$$Q = 2r(r+1) \sum_{i=1}^{r-1} \left( \frac{Y_{(i)}}{t} \right) \left[ \left( \frac{Y_{(i)}}{t} \right) - \left( \frac{Y_{(i+1)}}{t} \right) \right] + (r^2 - 1).$$

Replacing $t$ by its corresponding random variable $T$, we suggest the test statistic as

$$Q^* = 2r(r+1) \sum_{i=1}^{r-1} W_i(W_i - W_{i+1}) + (r^2 - 1),$$

where $W_i = \left( \frac{Y_{(i)}}{Y_{(r)}} \right)$. The mean and variance of the test statistics under $H_0$ is given by

$$E(Q^*) = r - 1 \quad \text{and} \quad V(Q^*) = \frac{4r^2(r-1)}{(r+2)(r+3)}.$$

Since we could not find the expression for $E(Q)$ under $H_1$, we observed the direction of the test statistics by simulating its values for different $n$ and $\beta$ and under different censoring proportion $p(=r/n)$, $0 < p < 1$. They are presented in Table 1.

**Table 1: $E(Q^*)$ for different values of $\beta$.**

<table>
<thead>
<tr>
<th>$n$</th>
<th>0.4</th>
<th>0.6</th>
<th>0.8</th>
<th>1.0</th>
<th>1.2</th>
<th>1.4</th>
<th>1.6</th>
<th>2.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>15.36</td>
<td>13.30</td>

<td>28.99</td>
<td>39.58</td>
</tr>
</tbody>
</table>

(The first value corresponds to 10% censoring and second value corresponds to 20% censoring).

The table shows that $E_{H_1}(Q^*) > E_{H_0}(Q^*)$ for $0 < \beta < 1$ and for all $n$. For $\beta > 1$, $E_{H_1}(Q^*)$ decreases below $E_{H_0}(Q^*)$ for some range of $\beta$ and then increases for $\beta > 1.4$. Thus the test procedure is to reject $H_0$ for large values of $Q^*$ in the above ranges.

### 3 Simulation study

We obtain the upper tail percentile points of the distribution of $Q$ by Monte Carlo method by generating 5000 random samples of different
sizes \( n \) from weibull distribution with \( \theta = \beta = 1 \) and then construct type-2 with replacement censored samples under different censoring proportions. The results are given in Table 2.

Table 2: The upper percentile points of the distribution of \( Q^* \).

</tr>
</tbody>
</table>

We also compute the power of the test for different values of \( \beta \) and \( n \). The proposed test is compared with the test proposed by Bain and Engelhardt (1986), say BE test and is given as follows: A size \( \alpha \) test for testing \( H_0 : \beta \leq \beta_0 \) against \( H_1 : \beta \geq \beta_0 \), the test reject \( H_0 \) if 
\[
cr(\beta_0/\hat{\beta})^{1+\beta^2} < \chi^2_{\alpha}(c(r-1)),
\]
where \( c = 2/[(1 + p^2)^2pc_22] \); \( p = r/n \), \( c_22 \) is the asymptotic variance of \( (\hat{\beta}/\beta) \) and \( \hat{\beta} \) is the MLE of \( \beta \). The values of \( c_22 \) is well tabulated (see Bain and Engelhardt, 1986) for different values of \( n \) and \( p \). Table 3 present the values of the powers of \( Q^* \) and BE test correspond to \( \beta > 1 \) for 5% level of significance under different censoring schemes.

Table 3: Power of the test for IFR alternatives

<table>
<thead>
<tr>

<td>.949  .935</td>
</tr>
</tbody>
</table>

(The first value corresponds to 10% censoring and second value corresponds to 20% censoring).
From the above table it is seen that as the values of \( n \) and \( \beta \) increases the power of the proposed test fairs better than the BE test. Table 4 presents the powers correspond to \( \beta < 1 \) for \( Q^* \) test for both 1% and 5% level of significance.

Table 4: Power of the test for DFR alternatives

</tbody>
</table>

(The first value corresponds to 10% censoring and second value corresponds to 20% censoring).

Thus from the above tables it is observed that the proposed test performs well for identifying both IFR and DFR alternatives under with replacement censored samples.

4 Example

We consider the data recorded based on a life test for a new insulating material. 25 specimens were tested simultaneously and the test was run until 15 of the specimens failed (for more details, see example 7.13 of Meeker and Escobar, 1998). Assuming that the data were recorded under with replacement scheme, we obtain the percentile points correspond to \( n = 25 \) and \( r = 15 \) as 62.83 and 88.14 respectively for upper 5% and 1% percentile points. Under the null hypothesis, the computed value of \( Q^* \) is 112.78, which is larger than the percentile points corresponds to 1% and hence the test is rejected. The p-value correspond to this test is 0.004. The power corresponds to the specific alternatives say, \( H_1 : \beta = 1.8 \) correspond to 1% and 5% are 0.11 and 0.18 respectively. Similarly, for \( H_1 : \beta = 0.5 \), the powers are obtained as 0.24 and 0.35 respectively for 1% and 5% cut-off points.
